The latest advancement of laparoscopic minimally invasive surgery in the last couple years is the single port (SPL), also known as a single-incision laparoscopic surgery (SILS) or laparoendoscopy single site surgery (LESS surgery). The LESS technique is laparoscopic surgery performed by only one incision, usually in the umbilical region. The laparoscope and tweezers are introduced through this single incision to perform the procedure. Initial studies have shown that the technique is reliable and applies to the areas of general surgery and urology. The use of LESS in gynecologic surgeries is recent and the number of cases reported in the literature remains low, respectively. Still, pioneering groups have observed promising results with LESS in both, simpler procedures such as salpingectomy and oophorectomy, and more complex such as hysterectomies and pelvic lymphadenectomy.

**CASE DESCRIPTION**

Patient, 44 years old, married, complaining of dysmenorrhea and chronic pelvic pain for about two years with progressive worsening. She presents hypermenorrhea and menorrhagia for one year. She was referred for hysterectomy with the diagnosis of diffuse adenomyosis. She had two normal pregnancies and two natural births. Her personal history includes a laparoscopy 11 years ago to treat fibroids and ovarian endometriosis. Her pap smear was negative for neoplastic cells.

On physical examination the patient was in good general condition, with body mass index of 29.6 kg/m². Genital examination showed a normal vulva and vagina. The bimanual digital pelvic examination showed an anteversion-flexion uterus (AVF), increased in size, mobile and with painful mobilization. The ovaries were normal in size and location without pain in mobilization. The pouch of Douglas exam was painful but without palpable nodules. The patient underwent a transvaginal ultra-

**LEARNING OBJECTIVES**

- Determine what equipment is necessary when performing a laparoendoscopy single site total hysterectomy
- Identify the appropriate instruments needed for this operation
- Note the postoperative considerations and possible complications
- Discuss the history and timeline of LESS procedures
- Access the benefits of laparoendoscopic surgeries
sound examination that showed an AVF uterus, heterogeneous myometrium with echogenic areas, diffuse and isolated cystic areas in the anterior wall that is thickened. Uterine volume is 142cm³. Endometrium was echogenic, regular with 11mm thick. Normal ovaries. After the diagnosis of diffuse adenomyosis, clinical treatment introduced. It was done using continuous combined estrogen and progesterone contraceptive pills, continuous oral progesterone or anti-inflammatory drugs. However, no significant improvement of clinical symptoms was observed and side effects hormone therapy forced discontinuation of treatment. It was then indicated a total hysterectomy. After orientation, the patient opted for laparoscopic hysterectomy. The patient was offered the possibility of LESS surgery that was accepted by patient. Prior to the appointment and the procedure, the patient signed an informed consent form (ICF) for surgery and another ICF allowing the publication of the case.

**OPERATIVE PROCEDURE**

The patient went under general anesthesia with endotracheal intubation and was placed in a supine position with legs parted. After antisepsis, a vesical catheterization was performed. A disposable intrauterine manipulator was introduced through the channel port and then a 5mm curved forceps and an ultrasonic scalpel was introduced into the other two channels.
introduced and a scalpel was used to perform a 2.5 cm longitudinal incision to open the peritoneal cavity. A LESS port disposable model was introduced and carried through the CO2 infusion to formation of pneumoperitoneum. After establishing the pneumoperitoneum pressure of 14mmHg, the patient was placed in lithotomy with Trendelenburg to displace and protect the rectum and bowel. The laparoscope 10 mm with flexible tip was introduced through the channel port and then a 5mm curved forceps and an ultrasonic scalpel was introduced into the other two channels.

With the entire abdominal cavity in view, the hysterectomy procedure begins. An ultrasonic scalpel is used to perform the ligation and section of the adnexal pedicles and round ligaments. The broad ligaments and peritoneum fold of the bladder are held as the bladder is lowered. The uterine arteries are identified, ligated and divided with an ultrasonic scalpel, followed by the opening of the vagina and removing the uterus. The vagina is anchored to the uterosacral and cardinal ligaments with a laparoscopic needle holder and an absorbable suture. Once this step is complete, the uterus and adnexa are removed and the closing of the vagina begins. Trocars remain in place and the abdomen is resufflated with CO2 and the surgeon checks for hemostasis. The pelvis is irrigated and suctioned and the pneumoperitoneum is released. The trocars are released and the umbilical incision was closed with stitches in the aponeurosis with polyglactin 910 and 4-0 suture.

POST-OP

This surgery was uneventful, and the patient recovered well after surgery with no complaints of significant pain and showed no immediate complications. The patient was discharged in good condition within 40 hours postoperatively.

OTHER POSTOPERATIVE CONSIDERATIONS

Patients are transferred to the PACU and monitored for fluid maintenance and pain. A liquid diet is recommended for 12 to 24 hours following the operation to assist with limiting nausea and slowing of gastrointestinal activity. The bladder may be drained if spontaneous voiding does not occur. After the patient is given a good prognosis, he or she may return to normal activities within a week.

Complications from this procedure can include hemorrhaging, failed LAVH and conversion to laparotomy, injury to major blood vessels, bowel injury, ureteral injury, bladder

---

VAGINAL AND LAPAROSCOPICALLY ASSISTED VAGINAL HYSTERECTOMY (LAVH)

**Equipment**
- Allen stirrups
- Electrosurgical unit
- SCD pump
- Video system
- Laparoscopic irrigator/suction
- Bipolar generator

**Instruments**
- GYN laparoscopy set
- Laparotomy instrument set
- Abdominal hysterectomy set
- D&G set
- Camera

**Supplies**
- LAVH supplies including any disposable or nondisposable laparoscopic supplies such as trocars, Veress needle, acorn cannula, endoscopic scissors, graspers, dissectors
- Gloves
- Surgeon-specific sutures
- Blades
- Basin set
- Dressing material according to surgeon preference
- LAVH drape

**Operative Preparation**

**Anesthesia**
- General anesthetic

**Position**
- Low lithotomy position
  - with Allen stirrups

**Prep**
- Abdominal and vaginal prep
- Patient is catheterized

**Draping**
- Drape sheet under the buttocks
- Leggings
- LAVH Laparoscopic drape sheet (may have attached leggings)

**Practical Considerations for Surgical Technologist**

Check all equipment and supplies prior to patient’s arrival
### Patient Safety – Lithotomy Position

<table>

</tr>
</thead>
</table>
| Crushing or shearing injury to the head                | - Place arms on armboards  
- If arms are positioned at the patient’s sides, the hands must be observed during movement of the operating table. |
| Pressure injury to skin,                               | - Pad feet and ankles  
- Be sure restraining devices are not restrictive  
- Avoid excessive torsion, flexion or extension of any part of the patient’s body  
- The legs may not come in direct contact with the stirrups  
- Adjust stirrups to an equal height and length  
- Raise and lower legs slowly and simultaneously by two individuals |
| blood vessels and nerves                               |                                                                                                                                                        |
| Back, knee and hip pain                                | - Buttocks should rest completely on the operating table  
- Adjust stirrups to an equal height and length  
- Raise and lower legs slowly and simultaneously by two individuals |
| Blood pressure changes                                 | - Raise and lower legs slowly and simultaneously by two individuals                                                                                 |
| Venous stasis                                          | - Use antiembolic devices                                                                                                                                |
| Cardiovascular and respiratory compromise              | - Restrict accompanying use of Trendelenburg’s position  
- Decrease leg height and hip flexion  
- Return patient to the supine position as soon as possible |
injury, wound infection and hernias at trocar sites. A longterm complication from this surgery can include developing vesicovaginal or enterovaginal fistulas.

AN OVERVIEW OF LESS

The first laparoscopic surgeries were performed by single port. Wheeless reported more than 4,000 cases of rapid and effective surgical sterilization by laparoscopy with only a single trocar incision28,29 about 20 years after the first complex procedure by a single trocar that resulted in a supracervical hysterectomy in four patients.22 However, the technique did not become a standard procedure at that time. The initial difficulties related to a lack of appropriate instrumentation, which evolved into the LESS stagnation.

In recent years there has been an increase in the interest of surgeons for the surgery by single port. The development of specific instruments and equipment for the LESS has contributed in the evolution of the technique. Reproducibility and safety of new materials has allowed the improvement of skill and performance of procedures of greater complexity.26 LESS surgery has been used in several procedures such as cholecystectomy, appendectomy, nephrectomy, colectomy, adrenalectomy, liver resection and bariatric surgery among others.

LESS surgery has been used in several procedures such as cholecystectomy, appendectomy, nephrectomy, colectomy, adrenalectomy, liver resection and bariatric surgery among others. In the following year, Yoon et al, reported performing supracervical hysterectomy by LESS with transcervical morcellation of the uterus.21

Kim et al, recently published a comparative study between LESS and conventional laparoscopy in cases of assisted vaginal laparoscopic hysterectomy.12 The patients who underwent LESS surgery had a lower score on the visual analog scale of pain post-surgery at 24 and 36 hours.12
Yim et al, published a study comparing hysterectomy for LESS (52 patients) and conventional laparoscopic hysterectomy (105 patients). The LESS group showed less intraoperative blood loss, shorter hospital stays and earlier introductions of solid diets. However, complications rates did not vary from each study. Chen et al, in 2011, published a randomized trial comparing LESS (50 cases) and conventional laparoscopic cases of laparoscopic assisted vaginal hysterectomy (50 cases). The authors concluded that there was no difference in operative time, blood loss, length of hospital stay and complication rate between the groups. However, the LESS group had less postoperative pain than the other group.

Jung et al, in a prospective randomized study of 68 patients who underwent conventional laparoscopy surgery or LESS, observed no significant difference in pain scores between groups. However, the LESS group used more analgesics than the laparoscopic conventional group.

A recent study by Escobar et al, demonstrated the use of LESS surgery in gynecological oncology surgeries. Twenty-one patients underwent pelvic and para-aortic lymphadenectomy staging for endometrial cancer and ovarian cancer. The authors concluded that the technique was feasible for such cases and that further studies should be conducted to assess the possible benefits of the new technique.

**The Future**

The possible advantages of using LESS surgery are related to reducing the number of auxiliary punctures. The effect of cosmetic (aesthetic) is a reality but can be quite questionable. The performance of only one umbilical incision of 20mm in LESS against the need for more auxiliary incisions in conventional laparoscopy in theory reduces the inherent risks in such punctures (bleeding, perforation of viscera or vessel and infection). Other advantages are the least reported postoperative pain, faster recovery times and shorter hospitalizations. However, these advantages still require confirmation with more studies, but this specific case confirms that the surgical technique for single portal is feasible, safe and reproducible and opens new perspectives in the treatment of gynecological diseases with minimally invasive surgical procedures.

SINGLE-SITE LAPAROSCOPIC TOTAL HYSTERECTOMY

343 July 2012 1 CE credit - $6

1. Advantages of laparoscopic surgeries include ___________.
   a. Shorter hospital stays
   b. Shorter recovery time
   c. Fewer complications
   d. All of the above

2. The patient needs to be placed in the ___________ position for a single-site laparoscopic hysterectomy.
   a. Supine
   b. Lithotomy
   c. Reverse Trendelenburg
   d. Kraske

3. A ___________ is used to perform ligation of the round ligaments.
   a. Electrosurgical pencil
   b. Scissors
   c. Ultrasonic scalpel
   d. Curved Forceps

4. Trocars remain in place as the surgeon checks for ___________.
   a. Hemostasis
   b. Instruments
   c. Blood pressure
   d. Hemolysis

5. Complications from this procedure can include ___________.
   a. Bowel injury
   b. Loss of appetite
   c. Nausea
   d. Loss of vision

6. With some of the studies that have been conducted, one of the biggest benefits for patients undergoing LESS procedures is ___________.
   a. Less operation time
   b. Less blood loss
   c. Less prep time
   d. Less postoperative pain

7. Following the procedure, the patient is monitored for ___________.
   a. Fluid maintenance
   b. Pain
   c. Nausea
   d. All of the above

8. If spontaneous voiding does not occur following the operation, the _________ may be drained.
   a. Wound site
   b. Bladder
   c. Bowels
   d. Stomach

9. During the procedure, a ___________ incision is performed to open the peritoneal cavity.
   a. Lateral
   b. Distal
   c. Longitudinal
   d. Inferior

10. The pneumoperitoneum is released after the pelvis is _________ and suctioned.
    a. Washed
    b. Irrigated
    c. Suctioned
    d. Scrubbed
